ABSTRACT

The increasing number of computer failures and crimes has forced managers to tighten the control procedures of their EDP systems. However the cost of an exhaustive control strategy is often very expensive, and its effectiveness is not guaranteed. This study designs and implements a Decision Support System that helps determine optimal control procedures for EDP systems (CEA-DSS).

The model base of the proposed DSS consists of various techniques for estimating computer exposures. The latter can be interactively analyzed via a Dialogue interface that supports tabular and graphic outputs. CEA-DSS also provides extensive database management capabilities to keep track of the diverse control problems. It is implemented in Pascal for the IBM-PC.

ACKNOWLEDGEMENTS

At the completion of this research the author wishes to express his gratitude as well as his personal sincere appreciation to professors T. X. Bui and N. R. Lyons for their assistance.

Furthermore he would like to express his sincere appreciation to his parents Antonios and Alexandra for their spiritual support.

Finally, the author dedicates this thesis to his wife Anastasia, who has always encouraged and helped him during his efforts for education and continuous self improvement.

I. INTRODUCTION

A. DEFINITION OF THE PROBLEM

Management's concern over adequate controls is useless if the data processing system designers, EDP auditors and their managers, do not have the proper training and control techniques to utilize when designing or reviewing the controls associated with computer systems.

No one has ever made a convincing estimate of the total cost of intentional and unintentional loss-causing acts associated with Electronic Data Processing (EDP) processes, but it is clear that the cost is high. Recently, many articles in professional journals as well as textbooks on EDP controls have been published responding to the urgency of protection and prevention of computer failures and frauds. Most of these studies focus on the identification of potential exposures, understanding of current control technology and the elaboration of EDP audit trails. These articles also refer to the importance of estimating costs and benefits, the integration of different audit processes, and the various natures of computer failures and corresponding protection and prevention measures [Ref. 1 and 2]. However a more formalized methodology remains to be desired.

As a consequence of this lack of formalized framework, the design of EDP control systems frequently relies on subjective estimations of the 'EDP controller' or the 'evaluator' for performing Cost-Effectiveness Analysis (CEA). This approach has two major disadvantages. First, the dense and complex inter-relationships between potential computer errors and related types of control procedures may make difficult, if not impossible, for the EDP auditor to capture the totality of the problem. Second, the combined

12

use of control procedures may cause uncontrollable and
undesirable effects. For example, over-auditing reduces the
throughput of the computer system due to delays caused by
redundant control measures, or under-auditing reduces the
protection effectiveness due to incomplete control measures.

B.   THE NEED FOR CONTROL AND SECURITY OF COMPUTER SYSTEMS

The management of an entity is responsible for
establishing and maintaining adequate controls. The
establishment and maintenance of a system of controls is a
significant management obligation.

A complex on-line data communication-oriented system
consists of various combinations of hardware, software,
facilities, people, and the policies and procedures that
interrelate these components. The many diverse components
and potential entry-points into a complex on-line system
make it possible for a person, with sufficient technical or
applications knowledge, to enter the system and make
unauthorized manipulations of data, programs, or operational
procedures. Furthermore, control procedures for an on-line
system cut across many lines of responsibility within an
organization, creating a control problem in itself.

As the number of more sophisticated computer installa-
tions increases rapidly, computers are taking on
increasingly responsible work. The more vital the work of
the computer, the more important is to protect it from
failure and catastrophe, and from criminals and people
who misuse its power. The following are typical cases of
critical computer implementations [Ref. 3]:

- A large city uses a computer for controlling its
  police operations. All police vehicles and ambulances
  are dispatched by men using terminals that inform them
  of the current emergencies. If the computer system was
  put out of action, many of the operations could not be
  controlled.

- 747s approaching a congested airport are prevented
  from colliding by a computerized air traffic control

13

system. The air traffic density has been allowed to increase to such a level that it could not be handled without the computer system.

- A variety of nuclear weapon systems are under computer control. The decision to launch a defensive nuclear attack is made by men reacting quickly to information from computer systems.

- Commercial data banks contain trade secrets and other information that could be worth many millions of dollars to the competitors.

Functions like these demand for data integrity, security and privacy. The data processing function must not loose vital data, introduce errors into them and permit unauthorized persons to read or modify the data.

C. SCOPE OF THE THESIS

A conventional life cycle of a computer audit process consists of the following six phases:

1. Information gathering.

2. Evaluation of current control technique.

3. Identification of new control measures or strategies.

4. Selection of control strategy.

5. Implementation.

6. Ex-post evaluation.

This thesis concentrates only on the fourth phase, the selection of control strategy, attempting to apply the Decision Support Systems (DSS) technology into the cost effectiveness auditing process.

D. OBJECTIVE

The objective of the thesis is to introduce a DSS for CEA. This may help EDP auditors and computer center managers to design successful EDP control and security systems, and monitor the effectiveness of the existing ones.

The issue of interactiveness seems to be critical in this context since the process of controlling EDP systems is

14

expected to be not frequent. The importance of interactive-
ness is further accentuated when EDP controllers face a
large combination of controls. Assuming that the DSS
learning curve of the end-user is low to none, the proposed
DSS emphasizes on the user friendliness of the system.

E.   CHAPTER OUTLINE

Chapter 2 gives a summary description of the CEA Model
that the DSS attempts to apply. The third chapter provides a
framework addressing user requirements and functions that
the DSS has to meet.

The fourth chapter is concerned about the detail design
of the Dialog Component of the system. The fifth chapter
discusses the design of the Model Component. The sixth
chapter describes the design of the Data Component, and the
seventh chapter focuses on the Database design which is part
of the Data Component.

The implementation of the DSS, along with implementation
problems encountered, is discussed in chapter 8. Chapter 9
gives an example of the system's operation simulating
the selection of control strategy process.

Finally, possible future extensions of the proposed DSS
and concluding comments are discussed in the last chapter.

II. THE CEA MODEL

The purpose of a cost-effectiveness analysis is to determine the most cost effective control strategy to reduce or eliminate potential errors and failures. It has been a generally accepted view that CEA is best used when it is integrated in the whole audit process. Some definitions of the basic concepts are necessary to the understanding of the CEA Model [Ref. 4].

A. DEFINITIONS OF BASIC CONCEPTS

1. The Concept of Exposures

The key element to start a CEA is not control but exposure. The concept of exposure is based on the assumption that the degree of vulnerability of computer systems may be reduced by enforcing EDP control measures, but cannot be totally eliminated due to some errors that remain unpredictable or unable to fully corrected.

2. Costs of Controls

Costs of EDP controls include all costs associated with the design, implementation and use of the controls. With experience gained in designing and implementing control systems, the costs become easier to be identified and quantified.

3. Benefits of Controls

The identification and quantification of benefits derived from control measures is very difficult. One way to look at benefits is to interpret them as a function control effectiveness.

16

4. Effectiveness of Controls

The effectiveness of a control is the extent to which this control can reduce or minimize the probability that an exposure occurs, reduce the damage if an exposure happens, and/or recover quickly from a damage. Therefore the reliability or performance of a control can be expressed as a percentage of control effectiveness relative to the related exposure.

5. Interdependencies between Controls

Often, a control, though primarily aimed at correcting a specific exposure, may affect one or more other exposures. Such interdependencies may dramatically affect the effectiveness of an EDP control system.

B. ASSUMPTIONS

The model assumes that the following conditions hold:

- Managers and auditors have limited time and capital resources for EDP controls.

- Each corporate computer system is characterized by its specific and unique control structure.

- Independence between potential failures or errors within a computer system.

- Each applied control is expected to prevent, correct or eliminate one or more potential errors, and/or affect others positively or negatively.

- Costs for EDP controls are known and quantifiable .

C. SUMMARY DESCRIPTION OF THE MODEL

Table 1 lists all the variables involved in the mathematic formulas of the model. The CEA Model consists of the following steps:

1. Define all Possible Control Sets

A control set is simply a combination of different available EDP controls. If there are n independent controls,

17

TABLE 1

DEFINITION OF VARIABLES USED BY THE MODEL

Symbol	Description
m	Number of potential errors or exposures
n	Number of individual control activities
a_i	Control activity, where $i = 1$ to n
c_i	Costs of implementing a_i
S	Number of control sets
s_k	Control set, where $k = 1$ to S
e_j	Potential error or exposure, where $j = 1$ to m
$Pr(e_j)$	Probability that e_j occurs
d_j	Amount of damage when e_j occurs
l_j	Expected damage caused by e_j
f_{ij}	Effectiveness of control a_i on exposure e_j
v_i	Expected benefits obtained from a_i
V_k	Expected benefits obtained from s_k
L_k	Expected loss resulted in using s_k
C_k	Costs of implementing s_k
TC_k	Total cost associated with s_k

the maximum number of control sets is defined as follows:

$$S = \sum_{i=1}^{n} [n! / (i! \cdot (n - i)!)]$$

This combinatorial approach provides an exhaustive identification of control sets. However, it may lead to a huge amount of possible combinations, when n becomes big.

2. Compute Expected Cost due to EDP Exposures

Expected losses due to occurrence of EDP exposures can be estimated using the weighted probability function, the P.E.R.T. method under the Accounting definition, and/or the ranking method.

Under the weighted probability, given an exposure, the probability of its occurrence, and the amount of its damage, the expected loss is defined as follows:

$$l_j = Pr(e_j) \cdot d_j$$

Under the P.E.R.T. method, given an exposure and the smallest($l1_j$), the most likely($l2_j$) and the largest($l3_j$) estimated dollar losses if the exposure occurs, the expected loss is defined as follows:

$$l_j = (l1_j + l2_j + l3_j) / 6$$

The Ranking method is based on two types of subjective rating scales related to the Rank P and the Rank Q. Rank P is the probability of occurrence of computer failures and Rank Q is the amount of damage caused by a potential exposure. Given P and Q, the expected loss can be computed as follows:

$$l_j = 10^{(P+Q-3)} / 4$$

3. Compute the Value of each Control Activity

The value of a control activity a_i is defined as the sum of the products between the expected amount of damage l_j and the effectiveness of a_i on exposure e_j:

$$v_i = \sum_{j=1}^{m} (l_j \cdot f_{ij})$$

4. Compute the Total Value of each Control Set

The calculation of the value of each control set must take into consideration joint effects of multiple control activity on single exposure. For all a_i contained in s_k:

$$V_k = \begin{cases} \sum_{i=1}^{n} \left(\sum_{j=1}^{m} (l_j \cdot f_{ij}) \right) & \text{if } f_{ij} > 0,\ f_{pj} = 0, \\ & \text{for all } p;\ a_p \in s_k \\[2ex] + \sum_{i=1}^{n} \left(\sum_{j=1}^{m} (l_j \cdot (1 - \bigcap_{i=1}^{n} \cdot (1 - f_{ij}))) \right) & \text{if } f_{ij},\ f_{pj} > 0, \\ & \text{for all } i \neq p;\ a_p \in s_k \end{cases}$$

5. Compute the Total Expected Loss for each Control Set

The enforcement of control measures is likely to reduce the probability of occurrence of computer failure and, consequently, the expected loss. However the reduction of expected loss is effective only on the exposures that are affected by controls. The computation of expected losses includes joint effects of control activities. Thus, for all a_i in s_k:

$$L_k = \begin{cases} \sum_{i=1}^{n} \left(\sum_{j=1}^{m} (l_j \cdot f_{ij}) \right) & \text{if } f_{ij} > 0,\ f_{pj} = 0, \\ & \text{for all } p;\ a_p \in s_k \\[2ex] + \sum_{i=1}^{n} \left(\sum_{j=1}^{m} (l_j \cdot (1 - \bigcap_{i=1}^{n} \cdot (1 - f_{ij}))) \right) & \text{if } f_{ij},\ f_{pj} > 0, \\ & \text{for all } i \neq p;\ a_p \in s_k \\[2ex] \sum_{j=1}^{m} l_j & \text{else} \end{cases}$$

20

6. Compute the Cost for each Control Set

The cost of the control set C_k, is the sum of the costs of the individual control activities in the set:

$$C_k = \sum_{i=1}^{n} c_i \qquad \text{if } a_i \in s_k, \; k = 1,S$$

7. Compute the Benefit Cost Ratio for each Control Set

The Cost Benefit Ratio of a control set s_k can be defined as the gross value of s_k (step 4) divided by the total cost of the set(step 6):

$$BCR = V_k / C_k \qquad \text{where } k = 1,S$$

8. Compute Total Expected Cost for each Control Set

The total expected cost for the control set is the sum of the total cost of control C_k plus the total expected loss:

$$TC_k = C_k + L_k \qquad \text{where } k = 1,S$$

9. Select the Optimal Control Set

The determination of an optimal control set depends on the selection criterion adopted by EDP managers or auditors. One can either choose the control set that minimizes the total expected cost(TC_k) or the one that maximizes the Benefit Cost Ratio(BCR). BCR represents the amount of benefits obtained per unit of cost of the investment.

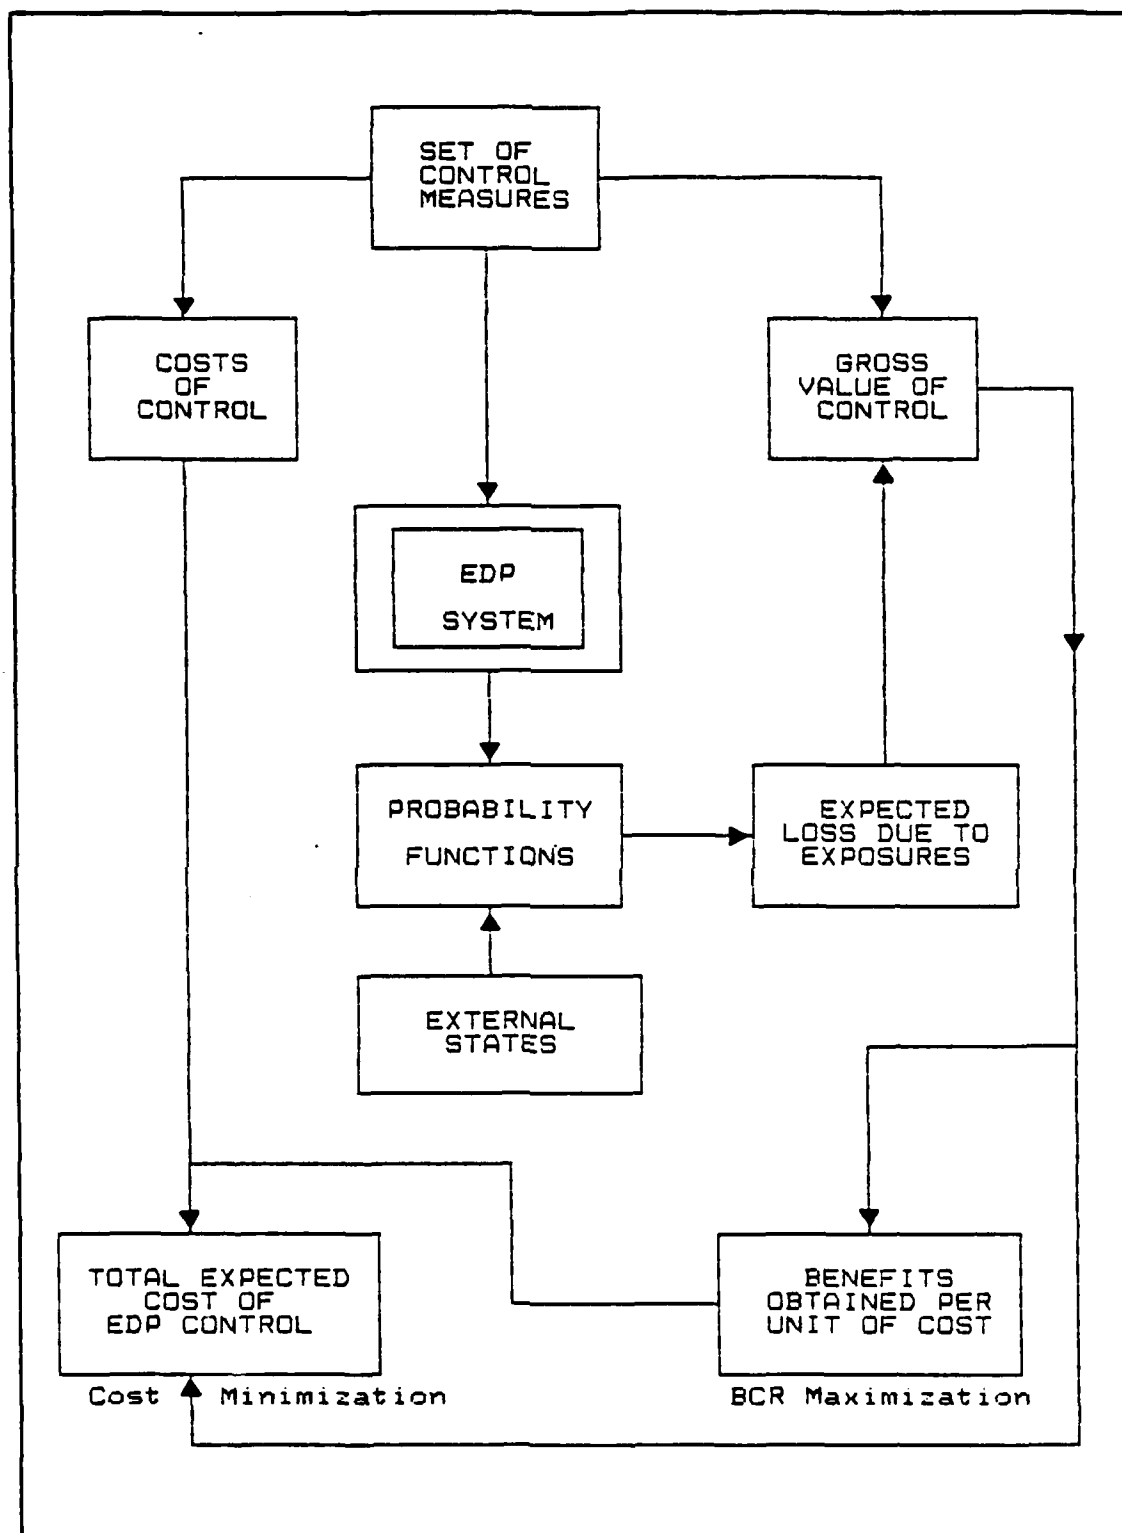

Figure 2.1   The Process of the CEA Model

III. THE DSS FRAMEWORK

The literature on DSS agree upon the emergence of the three main components of a DSS: the Dialog component, the Model component and the Data component. The separation of these components can result in simplicity of development and maintenance [Ref. 5]. Although these advantages are extremely desirable, there are cases where the complexity of the model component makes the complete separation ineffective.

The CEA-DSS falls in that category because the nature of the CEA Model requires a fairly complex and restrictive User Interface. The Quick-hit development strategy, according to which the DSS has been developed, consists of using the latest technology to quickly design a low-cost system for immediate pay-off [Ref. 6].

A. THE ROLES AND FUNCTIONS OF THE CEA-DSS

From the decision maker point of view, the user may expect CEA-DSS to perform the following functions:

- Save substantial amount of time to generate the numerous alternative control combinations.

- Support him or her to evaluate the alternatives and choose among them the alternative that fits better at the particular situation according to the available budget.

- Provide the capability to monitor EDP control and security systems in terms of Cost-Effectiveness.

- Provide graphical and tabular analyses to help the decision maker select close alternatives.

From a system analysis viewpoint , CEA-DSS essentially performs the roles of data analysis and generation of expected costs and benefits of control strategies. Data analysis also allows the decision maker to sort the data.

B. THE SYSTEM RESOURCES

Decision processes are dependent on variations in decision makers, i.e. users, as well as types of problems or tasks. Observations on decision makers indicate that:

- Many users have trouble describing a decision-making process. They seem, instead, to rely on conceptualizations, such as graphs or tables, when making or explaining a decision [Ref. 7]. Thus the DSS must help the user to conceptualize a problem.

- Users need memory aids [Ref. 8]. These memory aids may be physical, such as scratch paper, memos, or reports. The DSS should provide memory aids compatible with their needs. Directories, databases, workspaces, triggers are some typical memory aids the DSS should provide the user.

- Users have different styles, skills and knowledge [Ref. 9]. Therefore, if the DSS is designed to support a specific process, it would probably support a specific set of styles, skills and knowledge.

- Users expect to exercise control over the DSS. Direct control of the DSS allows the DSS to satisfy the different styles mentioned above. The user must understand what the DSS can do and be able to interpret its outputs.

IV. THE DIALOG COMPONENT

The dialog component is the most elegant part of the DSS design. There are no absolute rules or algorithms for the design process. It is often left upon the intuition of the designer to balance user requirements with system requirements and provide the optimal dialog component.

The dialog component of the CEA-DSS consists, at least conceptually, of the following three main units:

- The user interface.
- The intermodule linkage.
- The control.

A. THE USER INTERFACE

The user interface unit provides the link between the user and the system. Its primary concern is to make the system 'user friendly'. Even if a DSS provides extremely powerful functions, it may not be used if the user interface is unacceptable.

For the CEA-DSS a full screen frame is the standard presentation of the system to the end-user. The user, having only one screen format to deal with, gets familiar with the system faster.

The man-machine interaction is carried out through menus, questions/answers, messages, input/output forms, graphics, printed reports and a help facility.

1. The Frame

Figure 4.1 shows the frame of the CEA-DSS. It is divided into the following areas:

- The PROBLEM area. In this area appears the description of the problem currently processed.

- The ACTION area. This area informs the user about which part of the system is currently accessed.

- The WORK area. This is the place where the greatest part of the dialog is accomplished. All the menus, messages, input/output forms and the directory of the DSS appear here.

- The SUBMENU/SELECTION area. In this area appear submenus in line format and the user is asked to make a selection. This area is also reserved for question/answers and the 'press any key..' prompt, reminding the user that the system is waiting for some action.

Figure 4.1   The Frame of the CEA-DSS

2.   The Menus

The menus of the CEA-DSS are organized in a four level tree hierarchy. The root of the tree is the MAIN MENU of the system. From this menu can be called any menu that belongs in the second level. The latter contains has the DATABASE MENU, the MODEL MENU, and the SENSITIVITY ANALYSIS MENU. The third level consists of the database submenu, the

26

CONTROL STRATEGY MENU, the GRAPHICS MENU and the PRINT MENU. Finally, in the fourth level there are the control strategy, the graphics and print submenus. Figure 4.2 shows the tree hierarchy of the menus.

One level at a time, upwards or downwards, is allowed for the same branch of the tree. Changes from one branch to another require the control to be routed up to the root of these two branches. Although this is a little restrictive for the user, it improves the indermodular independence and, consequently, the overall control and clarity in the system.

All the menus, submenus not included, have their own help command which the user may use to get some useful information about the area of the DSS he/she is currently accessing. Most of the menus are discussed in Chapter 9.

3. Questions/Answers

There are a few questions/answers in the CEA-DSS. They are used either in cases where the system must be reassured that the user made the correct selection, or for single data entries.

4. Messages

Messages, almost always, appear at the center of the work area accompanied by a 'beep' sound. Messages, according the reason of their initiation, fall into the following three categories:

- Trigger Messages. These remind the user that certain operations may need to be performed that the system cannot accomplish.

- Informal messages. They inform the user about what process is the system performing. The primary concern of this category is to cover the gaps in the dialog caused by time consuming processes.

- Error Messages. They are initiated when the user supplies the system with incorrect entries. While editing exposures or controls, 'beep' sounds notify the user for entry errors.

27
Figure 4.2   Menus' Tree Hierarchy

All messages along with the reason that causes their initiation are listed in Appendix A.

5. Input/output Forms

The system needs only three forms for its operation. Two of them are input/output forms and one output form. One input/output form is dedicated to the Control activities and the other one to the Exposures. Both are used by the Database Management System for editing purposes. The output form is used by the Sensitivity Analysis for presenting the most effective or most cost effective Control Strategy.

Figure 4.3 shows the two input/output forms. Fields filled with Xs indicate that any character is valid, while 9s represent numeric characters only. Notice that the control input/output form is a variable one. The number of the "Effectiveness on Exposure" fields that appear on the form depends on the number of Exposures.

6. Graphics

The objective of the graphics part is to help the user conceptualize the differences among alternatives over the cost range he/she prefers. Graphics can also be used to supply parameters for the operations. For example, a point selected on a graph can identify a key value that will be used to retrieve detailed information. Representations like curves and histograms are the most appropriate for this particular application.

7. Printed Reports

Although not technically a part of the DSS, printed reports are aimed to provide the user with an easy-to-read summary of the processed problem. This summary consists of the exposure table, the control table and the listing of the sets generated by the model. The user may select any of these reports or all of them to be printed.

8. Help

The purpose of the help facility is to provide the user with on-line information about the specific area of the system he/she is currently accessing. Each help, one for each menu, is written in such a level of detail that enables its presentation in one full screen frame only. All help documents appear in Appendix B.

B. THE INTERMODULE LINKAGE

This unit assures the liaisons with the model and the data component. Usually, it is maintained by a set GOTO, CASE and IF_THEN_ELSE statements. Its nature and structure are highly dependent on the programming language and the hardware configuration being used for the CEA-DSS.

C. THE CONTROL

On the one hand, as in section 3.B stated, users expect to exercise control over the DSS. On the other hand, the system has to control its processes to assure an error free operation, not affected by incorrect entries and requests. The control unit is the part of the dialog component which bridges these two requirements. It is the filter between the user interface and the intermodule linkage unit. Validation of input data and verification of user requests are its primary functions. All the error messages are initiated by this unit. Finally, it can be stated that the control unit provides the boundaries within which the user is allowed to control the process.

V. THE MODEL COMPONENT

The most important units of the model component are the Model Base, the Model Base Management, the Model execution, the Sensitivity Analysis, the Dialog Interface and the Data Interface.

A. THE MODEL BASE

The following five routines, required for the CEA Model, are the content of the model base for the CEA-DSS. (The mathematical definition of these methods was discussed in section 2.C).

1. The Weighted Method

This routine computes the expected cost due to EDP exposures using the weighted probability function. It retrieves the required data, directly from the data base, manipulates the data and stores the results in memory for subsequent computations.

2. The P.E.R.T. Method

It is exactly the same with the Weighted Method routine except that it uses the P.E.R.T. method to compute the expected cost due to EDP exposures.

3. The Ranking Method

Similar to the others, it computes the expected cost due to EDP exposures using the Ranking Method.

4. The Effective Control

The role of this routine is twofold: To compute the Value of each Control activity and, if possible, to reduce

the number of the control activities that will be actually used in the generation of the control sets. The routine, having the results of one of the tree methods, retrieves, directly from the database, data related to the Control activities. For each Control, it computes first the value and then, it compares that value with the associated cost. If the value is greater that the cost, the result is sent to a secondary storage for subsequent computations. If the value is less or equal to the cost, the Control activity is ignored.

5.   The Control Sets

The output of the Effective Control routine is used by the Control Sets to generate the control sets. For each control set it computes the steps 4 to 8 described in the CEA model. If the Total Value of the set is greater than its cost, the set is stored in the database for decision analyses support, otherwise it is ignored.

B.   THE MODEL BASE MANAGEMENT

The role of the Model Base Management is to coordinate the model base and the data analysis functions. Since the CEA-DSS is aimed to support only the model described in Chapter II, the Model Base Management does not provide for on-line modeling or model update and restructure.

Its most important function is to enable the user to utilize the model base fully for decision support and to perform analysis of the results. This function is performed by iterative rerun of the model.

Also, it is responsible to update the Problem record, kept in the directory of CEA-DSS, with key information about the model runs. Thus, any future reference to this problem will not require any model execution, except if modifications take place on the initial data or on the cost range.

33

C. MODEL EXECUTION

Contains statements to call routines from the model base. It controls the execution of the model assuring the logical sequences of computation.

D. SENSITIVITY ANALYSIS

The Sensitivity Analysis unit helps the user analyze the results of the model runs. It is directly controlled by the dialog component. This unit consists of all the routines associated with graphic representations, control strategy selection and hard copy reports.

Input data for the sensitivity analysis are the control sets in the set files. As stated earlier, a model run may produce thousands of control sets. Therefore, it is usual several control sets to have exactly the same cost. Since the amount of data is huge and the analysis is primarily based on costs, the control sets in a set file must be indexed on their cost. This creates the requirement for the database system to provide for direct file access and to allow the existence of duplicate keys within the same index.

E. DIALOG INTERFACE

The model component is directly interfaced with the dialog component in order the user to gain control over its processes. He/she is able to select the desired statistical method and cost range for a model run and the cost range for the data analysis process.

F. DATABASE INTERFACE

The model component is directly interfaced with the data component. This enables the model component to create and delete the set files where the generated control sets are stored.

34

VI.   THE DATA COMPONENT

The data component consists of two main units. The the Database Management System and the Database discussed in the next chapter.

A.   THE DATABASE MANAGEMENT SYSTEM (DBMS)

The complexity of the Dialog component and the Model component, as well as the effective and efficient operation of the system lead to the selection of a Relational Database system. One characteristic of a Relational Database is the use of fixed length records. However, variable length records cannot be avoided. Since the data component requires functions like addition, deletion and modification on data, the elimination of modification anomalies seems to be of high priority.

The DBMS provides capabilities for sequential, indexed sequential and direct file access. Indexes are organized as B-trees. In a B-tree, a data unit is accessed by using a key. Any given key, primary key, is related to one and only one data unit in a data file. The system permits also the existence of duplicate keys or secondary keys, which are of great importance for the sensitivity analysis as discussed in the previous section.

B.   FILES USED BY THE SYSTEM

Files in the system can be divided into three categories, according to their initial creation:

- Files created by the data component. These are the directory of the system and its index. The directory contains all the problems available in the system's library indexed on their description. Duplicate problem description is not permitted.

- Files initiated by the user. The Controls file and the Exposures file fall in that category, indexed on their 'index'. Index is a unique key generated by the DBMS for management purposes. It keeps track of modification anomalies and makes the user's work easier. Actually, it identifies the current position of the data unit in the data file and NOT the data unit itself.

- Files created by the model execution. Each time the model is executed for a specific method, a set file is created indexed on set cost. Duplicate keys are necessary here because it is possible several sets to have the same cost. These files cannot be modified by the user or the system.

C. FILE CREATION/RETRIEVAL

The Data component has the flexibility to deal with library of problems and not with only one problem. In order to achieve that, it must have the ability to recognize and retrieve the files related to the problem in request, or to create files for that problem, if it is not found in the directory of the CEA-DSS. The algorithm followed is the following:

- The directory of the system has the fixed file name 'PROBLEM'. The data file has the fixed filetype 'DTA' and its index the 'IDX'.

- All the files created for one problem have as file name the description of the problem.

- The controls file has as filetype the 'DCL' and its index the 'ICL'.

- The exposures file has as filetype the 'DXP' and its index the 'IXP'.

- For the set files the algorithm used is more complicated. Additionally, the DBMS must be provided with an identifier indicating the method to which the set file refers. For that reason, the filetype for set files is separated into to fields. The first one, one character long, identifies the method, and the second one, two characters long, identifies the data file or the index. For the first field, the letters 'W','P' and 'R' correspond to the Weighted, Pert and Ranking method. For the second field, the 'DT' denotes the data file and the 'IC' the index file.

VII. DATABASE DESIGN

To some extent, Database design is an intuitive and artistic process. There is no algorithm for it. Typically, it is an iterative process. During each iteration, the goal is to get closer to an acceptable design. The database design is divided into two phases: logical design, where the needs of user are specified, and the physical design, where the logical design is mapped into the constrains of particular program and hardware products.

A. LOGICAL DATABASE DESIGN

1. Logical Database Records

The database of the CEA-DSS is required to maintain four different kinds of records. The first one, the PROBLEM record, is the data unit of the system's directory. Each problem has its own unique record. This record, except the problem description, contains key information about the most recent execution of the model on that problem. The second, is the EXPOSURE record. This record contains the description of the exposure and weights for the three methods. The third, the CONTROL record, has the description, the associated cost and elements indicating the effectiveness of the control activity on different exposures. The last, the SET record, is the output of the model execution and contains the combination of the control activities, and the results of the model run. Field descriptions for the logical database records are shown in Table 2.

Constraints on data items appear on Table 3. These constraints are limitations on the values that database can have. They are divided into three groups. Field constraints limit the values that a given data element can have.

37

TABLE 2

LOGICAL DATABASE RECORDS

Field	Description

PROBLEM Record:

Problem_Description	Alphanumeric, 8 characters
Problem_Creator	Alphabetic, 25 characters
Problem_Date	Format MM/DD/YY
Controls_for_ Weighted_Method	Numeric(integer), 2 digits
Controls_for_ P.E.R.T._Method	Numeric(integer), 2 digits
Controls_for_ Ranking_Method	Numeric(integer), 2 digits
Weighted_Method_ Total_Cost_of_Controls	Numeric(integer), 10 digits
P.E.R.T._Method_ Total_Cost_of_Controls	Numeric(integer), 10 digits
Ranking_Method_ Total_Cost_of_Controls	Numeric(integer), 10 digits

EXPOSURE Record:

Exposure_Description	Alphanumeric, 50 characters
Exposure_Damage	Numeric(integer), 8 digits
Exposure_Probability	Numeric(real), 5 digits
Smallest_Damage	Numeric(integer), 8 digits
Most_Likely_Damage	Numeric(integer), 8 digits
Largest_Damage	Numeric(integer), 8 digits
Exposure_RankP	Numeric(real), 5 digits
Exposure_RankQ	Numeric(real), 5 digits

CONTROL Record:

Control_Description	Alphanumeric, 50 characters
Control_Cost	Numeric(integer), 8 digits
Control_Effectiveness_ on_Exposure	Numeric(real), 5 digits

SET Record:

Set_combination	Numeric(binary), variable
Expected_Benefits	Numeric(integer), 10 digits
Expected_Loss	Numeric(integer), 10 digits
Set_Cost	Numeric(integer), 10 digits
Expected_Cost	Numeric(integer), 10 digits
Benefit_Cost_Ratio	Numeric(real), 5 digits

TABLE 3

CONSTRAINTS FOR LOGICAL DATABASE RECORDS

Field Constraints:

Problem_Description must not be null

Controls_for_Weighted_Method must not be 0

Controls_for_P.E.R.T._Method must not be 0

Controls_for_Ranking_Method must not be 0

Exposure_Probability must be from 0.000 to 0.999

Exposure_RankP must be from 0.000 to 7.000

Exposure_RankQ must be from 0.000 to 7.000

Control_Effectiveness_on_Exposure from 0.000 to 0.999

Benefit_Cost_Ratio must be greater than 1.000

Intrarecord Constraints:

Most_Likely_Damade greater than Smallest_Damage

Largest_Damage greater than Most_Likely_Damage

Interrecord Constraints:

Problem_Description must be unique

Exposure_Description may be unique

Control_Description may be unique

The number of Controls_for_Weighted_Method fields must
be equal or less than the number of Control records.
The same must be true for the Controls_for_P.E.R.T and
Ranking_Method.

The number of Control_Effectiveness_on_Exposure fields
must be equal to the number of Exposure records.

The level of the Set_Combination must be equal or less
than the number of Control records.

Intrarecord constraints limit values between fields within a
given record. Interrecord constraints limit values between
fields in different records [Ref 10].

2.   Logical Database Record Relationship

Figure 7.1 shows possible relationships among the
records used by CEA-DSS. This figure is a data structure
diagram. Single/double arrow notation is used to express a
one-to-many relationship and double/double arrow represents
a many-to-many relationship.
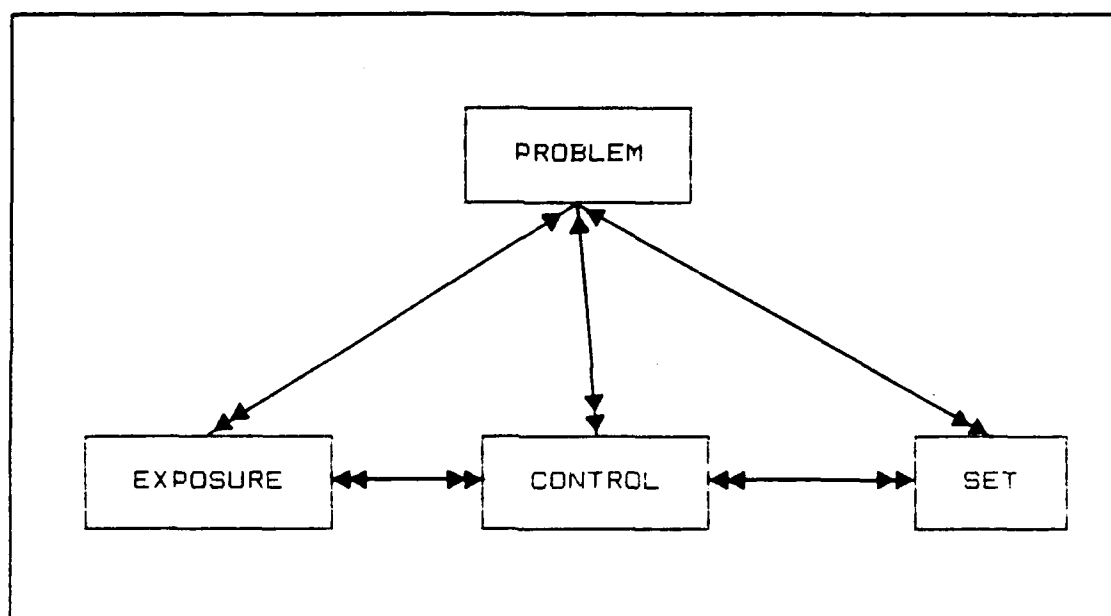

Figure 7.1   Data Structure Logical Diagram

The above complex network is further decomposed
into trees in order the database to be able to deal with
the data requirements. Figure 7.2 shows the decomposition
of the complex network. It is a four level tree structure
and represents relationships according to the model specifi-
cations. For clarity purpose, the Exposure is represented
with the letter 'E' and the Control with the letter 'C'.

40

The dashed lines connecting sets with controls and controls
with exposures indicate that it is not necessary for a set
to include all the control activities or a control activity
to influence all the exposures.
Figure 7.2   Decomposition of the Data Structure

3.   Data Manipulation in the CEA-DSS Database

The possible transactions and the data that the
transactions can change are listed in Table 4. Some transac-
tions change data, some add new data, some delete data and
some are simple queries. Queries are all the transactions in
the sensitivity analysis part. No data are modified.

TABLE 4

POSSIBLE TRANSACTIONS FOR THE CEA-DSS

Transaction	Data or Transaction Involved
NEW PROBLEM	Add one record in the directory
	Create Control and Exposure files
	Add, at least, two Exposures and two Control activities
DELETE PROBLEM	Erase Control and Exposure files
	Erase any existing Set File
	Remove the Problem record from the directory
	Erase the directory, if there is not another problem in it
ADD EXPOSURE	Add one record in the Exposure file
	Update records in the Control file
ADD CONTROL	Add one record in the Control file
DELETE EXPOSURE	Remove record from the Exposure file, if it has more than two records
	Remove references to this Exposure from the Control records
DELETE CONTROL	Remove record from the Control file, if it has more than two records
EDIT EXPOSURE	Modify record in the Exposure file
EDIT CONTROL	Modify record in the Control file
MODEL EXECUTION	Erase any existing Set file for the selected method.
	Create Set file
	Add Control Sets in the Set file
	Update record of the current problem in the directory of the syatr

42

B. PHYSICAL DATABASE DESIGN

During the second phase of the database design, the physical design, a transformation takes place. The logical schema is transformed into the particular data constructs that better satisfy the implementation requirements and constraints.

1. Design Constraints

One implementation requirement for the CEA-DSS is to be used on microcomputers. This requirement along with the other requirements, discussed in the framework, introduce the following constraints for the physical database design phase:

- Integer numbers are not allowed in the system. All numbers have to be of type real and will be stored in the system as strings of characters.

- The length of records in bytes must be limited as much as possible because of microcomputer limitations.

- Since the size of the Control record depends on the number of the Exposure records, the number of Exposures for one problem may be 24 at maximum.

- The number of control activities for one problem are limited to 13 at maximum. Three model runs, one for each method, for a problem having 13 control activities, may generate up to 24,576 set records. These records need at least 3 Mbytes to be stored.

2. The Physical Schema

The Physical database records are slightly differentiated from logical records to satisfy the design constraints. The field description of the records is shown on Table 5 where all numerics are of type real and the abbreviation 'char' instead of 'character' is used.

Keys are identified according to the data retrieval requirements. The record relationships and constraints emain the same as in the logical design.

The idea of having flat files in the database is infeasible because of the model's computational complexity.

43

TABLE 5

PHYSICAL DATABASE RECORDS

Field	Description
PROBLEM Record: Indexed on Problem_Description	
Problem_Description	Alphanumeric, 8 char
Problem_Creator	Alphabetic, 25 char
Problem_Date	Format MM/DD/YY
Controls_for_ Weighted_Method	Array(1..13) of 2 char
Controls_for_ P.E.R.T._Method	Array(1..13) of 2 char
Controls_for_ Ranking_Method	Array(1..13) of 2 char
Weighted_Method_ Total_Cost_of_Controls	Numeric, 10 char
P.E.R.T._Method_ Total_Cost_of_Controls	Numeric, 10 char
Ranking_Method_ Total_Cost_of_Controls	Numeric, 10 char
EXPOSURE Record: Indexed on Exposure_Index	
Exposure_Index	Numeric, 2 char
Exposure_Description	Alphanumeric, 50 char
Exposure_Damage	Numeric, 8 char
Exposure_Probability	Numeric, 5 char
Smallest_Damage	Numeric, 8 char
Most_Likely_Damage	Numeric, 8 char
Largest_Damage	Numeric, 8 char
Exposure_RankP	Numeric, 5 char
Exposure_RankQ	Numeric, 5 char
CONTROL Record: Indexed on Control_Index	
Control_Index	Numeric, 2 char
Control_Description	Alphanumeric, 50 char
Control_Cost	Numeric, 8 char
Control_Effectiveness_ on_Exposure(1..24)	Numeric, 5 char
SET Record: Indexed on Set_Cost	
Set_combination	Array(1..13) of 2 char
Expected_Benefits	Numeric, 10 char
Expected_Loss	Numeric, 10 char
Set_Cost	Numeric, 10 char
Expected_Value	Numeric, 10 char
Expected_Cost	Numeric, 10 char
Benefit_Cost_Ratio	Numeric, 5 char

44

More specifically, the use of flat files should increase dramatically the time required for a model run, something undesirable for a DSS.

Variable length records are used instead. This variability in length results in loss of storage capacity because the record occupies space equal to its maximum length regardless its actual length. This, off-course, is the primary disadvantage of the variable length records, but for that particular application is justified by the fact of time savings.

VIII.   IMPLEMENTATION OF THE CEA-DSS

One of the objectives of the implementation phase is to use the CEA-DSS with microcomputers.

A.   THE PROGRAMMING LANGUAGE

The complexity of dialog and data component underline the need for a structured programming language which can support character manipulations, screen management and, to some degree, mathematic calculations. Turbo Pascal (Version 2.0) was chosen for this particular implementation.

B.   SUPPORTING PACKAGES

Turbo Access Toolbox (Version 1.00) is used for the database management system. Turbo Access provides for sequential, indexed sequential and direct file access, allowing and the existence of duplicate keys in an index file. Turbo Graphix Toolbox (Version 1.00A) is used for the graphics part of the system.

C.   THE DATA FLOW IN THE CEA-DSS

In order to deal with the high complexity of the data and transaction flow, it was necessary to divide the system from the beginning into four major areas. This helped to draw the initial diagrams. Using these diagrams as the base, after reviews and refinements, the final software structure was derived. These four areas are the following:

1.   The Main Area

This area contains data flows and transactions occurring from the initialization of the system until the

main menu appear on the screen and the user make his/her selection. Figure 8.1 shows the refined flow diagram of the main area.

2. The Database

Figures 8.2, 8.3 and 8.4 are the flow diagrams of this area. It contains transactions and data flows related to the database management system, like updating control and exposure files, switching problems, and deleting problems.

3. The Model

The model area diagram, Figure 8.5, describes all the operations of the model execution. Figure 8.6, presents in detail the data flow during the generation of the control sets. This is the most important and most complex part of the CEA model and is included here for maintenance and future modification or improvement purposes.

4. The Sensitivity Analysis Area

Transactions and data flows associated with the decision support part of the CEA-DSS are illustrated in Figures 8.7, 8.8 and 8.9.

D. SOFTWARE STRUCTURE

The refined software structure, Figure 8.10, is a rearrangement of the flow diagrams from the perspective of the flow of control in the system. The requirement for the user to access control over the whole process, underlines the need for a hierarchical flow of control among the various processes of the system. Top-down is considered as the most effective design for the CEA-DSS since it results in a modular and highly cohesive software structure. Modularity and high cohesion facilitate the coding and maintenance phases.

57

E. IMPLEMENTATION PROBLEMS

The most serious implementation problems are problems associated with the memory management of a microcomputer. The capacity of the memory dedicated to the Central Processing Unit (CPU) is 64 Kbytes for a microcomputer. Consequently, the size of the program part called, along with all the type declarations and the supporting modules, must not exceed the size of the CPU's memory. This is a troublesome limitation when dealing with long programs.

This is the case for the CEA-DSS. The inclusion of the Turbo Access and Turbo Graphix packages within the actual program further limited the allowable size of its modules. Reduction of the module size implies a loose control hierarchy. An effort to reorganize the software structure resulted in undesirable control flow inefficiencies. Fortunately, Turbo Pascal provides for overlay organization which eliminates the memory size limitation.

A technique, called overlays, is used to allow the system to be larger than the amount of memory allocated to it. The idea of overlays is to keep in memory only those instructions and data that are needed at any given time [Ref. 11]. When other instructions are needed, they are loader into space that was previously occupied by instructions that are no longer needed. However, this technique suffers from the following limitations:

-   A module must first be loaded into the memory in order to be executed. This causes the system to run somewhat more slowly, due to the extra I/O operation to read the module. For this reason, it is recommended to load the CEA-DSS software on a hard disk or a ram disk. High access speed devices would result in considerable reduction of access time.

-   Since overlays share the same space in memory, a module cannot call modules which belong in another overlay of the same area. For example, a module calls another one from a different overlay. This overlay is loaded in place of the caller and the called module is executed. The problem is that after its execution the system is meshed because it does not find the caller to return.

This introduced additional problems to the original structure of the program. The inclusion of control code, like flags, labels, case and if then else statements, helped in establishing communications among the various overlays of the same area.

F. EFFORT DISTRIBUTION FOR THE CEA-DSS DEVELOPMENT

CEA-DSS was built in five months and required an effort of six man-months. Table 6 shows the distribution of the effort, in percentages, among the different phases of the CEA-DSS development.

TABLE 6

EFFORT DISTRIBUTION

Time	Activities
20%	Requirements Analysis and Initial Design
23%	Detailed Design
30%	Programming, Debugging and Testing
5%	Initial Testing and User's feedback
22%	Stepwise refinement of the components

IX.   A SESSION WITH THE CEA-DSS

The objective of this chapter is to illustrate the operation of the CEA-DSS. The figures in this chapter have been generated during the testing phase of the CEA-DSS on a IBM PC-XT microcomputer.

A series of screens has been suggested as the most effective way to describe step-by-step the system's basic operation.

STEP 1: Drive definition (Figure 9.1). The system has the flexibility to use a different drive for its database.

```
┌─────────────────────────────────────────────────────────────┐

```

Figure 9.2   Directory

When a new drive, i.e. a new floppy disk, is selected, the system creates a directory first, and then prompts the user to define the problem. For a pre-defined drive, a listing of the directory appears on the frame. The user may select a problem from the directory, or define a new one. In case of an existing problem selection, the process continues with Step 4.

STEP 3: Data entry (Figure 9.3). The system creates the control and exposure files for the particular problem. Then, the user has to provide the initial data. At least

```

Figure 9.4   Main Menu

STEP 5:   Model execution. The Model Menu, allows the
selective invocation of one of the three statistical methods
for a model run. The user may select one method or all of
them. Then, the system prompts the user to define the
desired level of cost according to which the generation of
control sets will be performed. The use of realistic cost
levels is recommended, since it may result in a considerable
reduction of the amount of control sets to be generated

63

and, consequently, in storage and I/O time. Figure 9.5 shows
the model menu and the cost level entry.

Figure 9.6   Sensitivity Analysis Menu

<u>STEP 7</u>: Print Reports. The system has the capability to produce three types of reports. It is expected that the user will use these reports, during the sensitivity analysis process, as reference. The first table (Figure 9.7) summarizes the initial data of expected losses caused by exposures, for three statistical methods. The second report (Figure 9.8) summarizes the control activities' effectiveness on exposures. Finally, control sets report is a listing of the file created and updated by a model run. Figure 9.9 shows the control sets generated according to the weighted method.

Figure 9.10   The Print Menu

STEP 8: Graphics. Curves and histograms help the user conceptualize the differences among alternative control sets and among different statistical methods. The incompatibility problem of the various types of printers does not allow the system to make hard copies of the graphs. The user can use instead the [PrtSc] key of the keyboard. Each graphics screen contains two graphs. The upper graph depicts the Benefit Cost Ratio versus Cost relationship, and the lower graph the Total Expected Cost versus Cost. Figure 9.11 shows the curves for the DSSTEST problem and Figure 9.12 the histograms. For readability purposes, on each curve can be drawn up to 200 points and on each histogram up to 24 bars.
69
Figure 9.11   Graphical Analysis using Curves

Figure 9.12   Graphical Analysis using Histograms

STEP 9: The last phase of the CEA-DSS process is the control strategy selection. The decision maker may select the most effective (Figure 9.13) or the most cost effective control strategy (Figure 9.14) within the cost range he/she desires. The decision maker, helped by the reports and graphs, is expected to have a better opinion about the amount to be spent for control measures.

```
| EFFECTIVENESS  OF  CONTROL  AND  SECURITY  OF  COMPUTER  SYSTEMS |
|--------------------------------------------------------------------|
| PROBLEM: DSSTEST        |    ACTION: SENSITIVITY ANALYSIS / CONTROL STRATEGY |

      WEIGHTED METHOD: THE MOST EFFECTIVE SET

  Total Expected Benefit :    32525     Total Expected Cost   :   115275

            Cost Benefit Ratio(BCR): 1.73

      Prior Expected Damage Due to Exposures:  147800
      Post  Expected Damage Due to Exposures:   70775

  press any key..                        Today is: 8/20/1985
```

Figure 9.13   The most Effective Control Strategy

The optimal solution in the problem is found when the selected control set is both the most effective and the most cost-effective over a predefined cost range. This is the case for this particular example. Figures 9.13 and 9.14 show the same control set. Under the "Most Effective" option, the control set with the lowest expected cost is selected. Under the "Most Cost-Effective" option, the set with the highest BCR is the most preferable. However,

the system does not provide any algorithm for combining these two options in order to indicate the optimal control strategy.

Figure 9.14   The most Cost-Effective Control Strategy

This is the basic process for a problem creation and analysis. Also, the user has the opportunity to access the database of the system through the Database Menu. He/she may modify the initial data, change problem and/or delete the problem. If modifications take place on the data, the model must be executed again. The deletion of the problem erases any file belonging to this as well as its record in the directory. After that, the main menu appears on the screen allowing the user to select one of the "Help", "Database" and "Exit to DOS" options. The other options of the main menu are prohibited when there is no problem definition. The database choice after a problem deletion or changing the

73

current problem cause the previously described process to be
repeated from the beginning. The database menu appears on
Figure 9.15.

X. CONCLUSION

The purpose of the research was to implement a DSS for selecting EDP control strategies. Three analytical methods for determining cost-effectiveness of EDP controls were integrated in a customized database management system. Also a careful user interface was designed to support user interactiveness with the system.

From the user's perspective, the current version of the CEA-DSS is able to handle any uneven condition associated with data entry and process request errors. The enhancement of an acceptable combination of colors and sounds contributes to the user friendliness of the system. Since the users have different preferences, one possible improvement should be to let the user define the colors and sounds he/she likes. The help facility also can be easily modified to satisfy the user needs for on-line information, as discussed in Appendix B.

From the system design perspective, CEA-DSS permits the user to exercise virtual control over its processes. The database system is exclusively designed and implemented to serve the introduced EXPOSURE, CONTROL and SET records. It is expected that any future enhancements in the database schema will require extensive modifications and maintenance to be done on the database and the DBMS. The model base of the CEA-DSS consists of the three variances of the CEA model. Integration of new techniques, using the existing data structure, will require slight modifications of the current system. The same is true for the sensitivity analysis part where any additional reports, graphs and control strategy selection algorithms will not influence the system.

75

One great inefficiency recorded during the testing phase is associated with the control strategy selection algorithm. The sample problem DSSTEST, presented in Chapter 9, can be considered as an extreme condition. The solution was recognized as the optimal one because it had both, the greatest Benefit Cost Ratio and the lowest Total Expected Cost. This is generally not the case. In reality, the optimal solution is found somewhere in the three dimensional spectrum composed of the Benefit Cost Ratio, the Total Expected Cost and a Scaling Relational Algorithm for them. It is expected that the enhancement of such an algorithm will dramatically improve the control strategy selection process.

Another unresolved issue concerns the assignment of the BCR to the control sets. Control Sets consisting of fewer Control activities turn out to have higher BCRs. This is due to the nature of the algorithm that the model uses to compute the value of the control sets. A way to handle this would be to introduce in the computation of the control set's BCR one more parameter which will be able resolve these differences.

It is recommended that the CEA-DSS built during this research be evaluated on real life applications. In effect, all data used during the testing phase of the CEA-DSS were chosen on a random basis. Information gathered from a real life computer audit process would probably contribute to the evaluation of current control techniques. Furthermore, the CEA-DSS will not only support the selection phase but also the evaluation and exploration phases of the computer audit process life cycle.

APPENDIX A

MESSAGES

CREATING EXPOSURE AND CONTROL FILES

Initiation: A new problem has been introduced by the user.

DELETING   CONTROL

DELETING   EXPOSURE

Initiation: Request for deletion of a control or exposure
            record.

NEW   DIRECTORY

Initiation: New drive definition.

CONTROL "description" IS NOT EFFECTIVE

Initiation: The cost of a control activity is greater than
            its expected value.

PLEASE   WAIT

Initiation: Control sets generation.

PLEASE WAIT FOR THE PREPARATION OF THE GRAPH

Initiation: Request for graphic representation, curve or
            histogram.

ERROR MESSAGES:

SYSTEM REQUIRES 2 CONTROLS AT LEAST

SYSTEM REQUIRES 2 EXPOSURES AT LEAST

Initiation: Request for deletion of control or exposure
record while the file contain only two records.

THE SYSTEM CANNOT HOLD ANOTHER EXPOSURE

Initiation: The user attempts to add the 14th control
activity or the 25th exposure.

YOU MUST RUN THE MODEL FIRST

Initiation: Request to access sensitivity analysis areas
prior to the model execution.

THERE IS NOT ENOUGH SPACE ON DRIVE X

Initiation: Nonexistent drive definition or the defined
drive does not have the appropriate space for a
dictionary and problem creation.

CHECK YOUR ENTRY. "HIGH" MUST BE GREATER THAN "LOW"

Initiation: Entry of an ambiguous cost range for the
sensitivity analysis part.

TRIGGER MESSAGES:

DEFINE THE DRIVE YOU WANT TO USE FOR FILES

Initiation: CEA-DSS activation or request to change the
current problem.

DO YOU WISH TO DELETE THE PROBLEM ?

Initiation: Request to delete the current problem. The
system prompts the user to confirm.

78

THERE IS ALREADY FILE FOR THAT METHOD

Initiation: Request to rerun the model. The user can delete the set file only, or to proceed to model execution.

CANNOT COMPUTE SETS WITHOUT EFFECTIVE CONTROLS

CANNOT COMPUTE SETS WITH ONLY ONE EFFECTIVE CONTROL

Initiation: Control sets generation. The user may correct some initial data or to abandon the current problem.

THERE IS NO ANY SET WITHIN THAT RANGE

Initiation: The cost range defined for sensitivity analysis is very limited. The user may widen the range.

CANNOT MAKE GRAPH WITH LESS THAN 2 SETS

Initiation: Request for graphics, while the defined cost range includes only one control set. The user may redefine a wider cost range.

APPENDIX B

THE HELP FACILITY

The help facility of the CEA-DSS is carried out via the HELP module, listed at the end of the program listing in Appendix C. The Help module supplies the calling menu with information relative to its functions. The algorithm for this selective retrieval of information is based on a code character. This character is sent to the Help module as parameter in the call statement, identifying the calling part of the program. The Help module uses this character to assemble the file name of the text file where the requested information resides.

The advantage of keeping the help text external to the program is that it can be changed easily, with any editor, without affecting the code of the CEA-DSS. The help module also has the advantage of returning control to the caller immediately in case that the requested help, text file, is missing. The files of the system dedicated to the help facility along with their content are listed below.

File: HELPM.TXT
H E L P   F O R   M A I N   M E N U

UPDATE FILES OR CHANGE WORK
This is the Database of the system. You have access to three files. The EXPOSURE, the CONTROL and the PROBLEM file. You can Add, Delete or Edit EXPOSURES and CONTROLS. You can also Change or Delete WORK.
RUN THE COST EFFECTIVENESS MODEL
Once you have updated the EXPOSURE and CONTROL files you can run the model. The model will create the set files

which will be used after for decision making. If you chose
the current work from the directory of the system and you
are not going to modify the EXPOSURE and CONTROL files you
DON'T need to run the model.

SENSITIVITY ANALYSIS

This is the main area of interest. It will help you to find
out the optimal solution according to your preferences and
budget. There are available to you graphics and print
facilities.

File: HELPD.TXT

H E L P   F O R   D A T A B A S E   M E N U

At the bottom of the frame it appears always the command
line which prompts you to make selections by typing numbers
or letters.

CHANGE PROBLEM

The directory of the system is listed and then you are
prompted to define the problem you desire. If you choose an
existing one, you will be switched to that immediately. If
you create a new one, you will be asked to enter, at least,
two EXPOSURES and two CONTROL ACTIVITIES.

DELETE CURRENT PROBLEM

You can only delete the current problem. If you wish to
delete a different problem, you must change the problem
first, and then choose from the directory the problem you
want to delete, and delete it. You will be asked to confirm
for the requested deletion by typing the character "!".

UPDATING EXPOSURE OR CONTROL FILE

You can A)dd, D)elete, E)dit Exposures and Controls, and
scroll the files forwards and backwards using N)ext or
P)revious.

Keep in mind that the edit mode is always in the INSERT
MODE.

File: HELPO.TXT

H E L P   M O D E L

You can run the model using the WEIGHTED PROBABILITY, the
P.E.R.T method and the RANKING method. You will be prompted
to enter the upper cost limit. If you have enough controls
in the control file it is better to use as short cost
ranges as possible in order to minimize the time that the
system will require to generate the control sets. Don't
forget that N controls may produce 2 to the Nth power
control sets.

If you get a message like 'NOT ENOUGH SPACE ON DRIVE X', you
can overcome that using one of the following:

1. If you have already run another method for that
problem, choose that method again, and erase its set file.

2. Change problem, choose one from the directory that you
do not need, delete it, and then choose again the problem
you want to work on.

File: HELPS.TXT

H E L P   F O R   S E N S I T I V I T Y   A N A L Y S I S

CONTROL STRATEGY

Control strategy helps you determine the optimal control
alternative from all the possible combinations of control
activities, or the best one, according to the cost range
you are asked to specify.

GRAPHICS

You can generate curves and histograms representing the
relations between BENEFIT COST RATIO and COST, or between
TOTAL EXPECTED COST and COST.

REPORTS

You can have a hardcopy of the exposures or controls in
tabular format, and a listing of tne set files.

File: HELPB.TXT

H E L P   F O R   C O N T R O L   S T R A T E G Y

MOST EFFECTIVE ALTERNATIVE

The most effective alternative is the one that it is expected to minimize the total expected cost.

MOST COST EFFECTIVE ALTERNATIVE

The most cost effective alternative is the one that will return the highest benefit per dollar spent.

File: HELPG.TXT

H E L P   F O R   G R A P H I C S

You can print the curves or histograms by using the [PrtSc] key. Be sure that your printer is ON. The system will switch it to the graphics mode.

Curves and Histograms represent relations of Cost versus Benefit Cost Ratio and Cost versus Total Expected Cost.

Each curve can hold up to 200 control sets to be drawn, and each histogram ut to 24.

You will be asked to give the Cost Range over which the graph will be done. If the number of control sets within the selected range exceeds the above limits, the system will adjust the range.

File: HELPP.TXT

H E L P   F O R   P R I N T   R E P O R T S

YOUR PRINTER MUST BE ON-LINE BEFORE YOU TRY TO PRINT ANY REPORT

You must have set the top of form properly and use page length 11 inches in order the reports to be printed correctly.
